Continuous soil attribute modeling and mapping: 
Caret

Soil Security Laboratory

2018

1 Advanced Work: Model fitting with Caret Package

It becomes quickly apparent that there are many variants of prediction functions that could be used for DSM. As was observed, each of the models used have their relative advantages and disadvantages. Each also has their own specific parameterisations and quirks for fitting. Sometimes for the various parameters that are used for model training are chosen without any sort of optimisation, even due consideration sometimes. Sometimes we might be confronted with many possible model structures to use, it is often difficult to make a choice what to use, and just default with a model we know well or have used often without considering alternatives. This is where the caret R package http://topepo.github.io/caret/index.html comes into its own in terms of efficiency and streamlining the workflow for fitting models and optimising some of those parameter variables. As the dedicated website indicates (http://topepo.github.io/caret/index.html), the caret package (short for Classification And REgression Training) is a set of functions that attempt to streamline the process for creating predictive models. As we have seen, there are many different modeling functions in R. Some have different syntax for model training and/or prediction. The caret package provides a uniform interface to the various functions themselves, as well as a way to standardize common tasks (such parameter tuning and variable importance). There are currently nearly 400 model functions that the caret package interfaces with.

First get the data and perform the covariate data intersection

```r
library(ithir)
library(raster)
library(rgdal)
library(sp)

# point data
data(HV_subsoilpH)

# Start afresh round pH data to 2 decimal places
HV_subsoilpH$PH60_100cm <- round(HV_subsoilpH$PH60_100cm, 2)

# remove already intersected data
HV_subsoilpH <- HV_subsoilpH[, 1:3]

# add an id column
HV_subsoilpH$id <- seq(1, nrow(HV_subsoilpH), by = 1)

# re-arrange order of columns
HV_subsoilpH <- HV_subsoilpH[, c(4, 1, 2, 3)]

# Change names of coordinate columns
names(HV_subsoilpH)[2:3] <- c("x", "y")

# grids (covariate raster)
data(hunterCovariates_sub)

Perform the covariate intersection.
coordinates(HV_subsoilpH) <- ~x + y

# extract
DSM_data <- extract(hunterCovariates_sub, HV_subsoilpH, sp = 1, method = "simple"
DSM_data <- as.data.frame(DSM_data)
str(DSM_data)
## 'data.frame': 506 obs. of 15 variables:
## $ id : num 1 2 3 4 5 6 7 8 9 10 ... 
## $ x : num 340386 340345 340559 340483 340734 ...

Often it is handy to check to see whether there are missing values both in the
target variable and of the covariates. It is possible that a point location does
not fit within the extent of the available covariates. In these cases the data
should be excluded. A quick way to assess whether there are missing or NA
values in the data is to use the complete_cases function.
which(!complete.cases(DSM_data))
## integer(0)
DSM_data <- DSM_data[complete.cases(DSM_data), ]

To begin, we first need to load the package into R:

```r
library(caret)
```

The workhorse of the `caret` package is the `train` function. We can specify the model to be fitted in two ways:

```r
# 1.
fit <- train(form = pH60_100cm ~ AACN + Landsat_Band1 + Elevation + Hillshading + 
              Mid_Slope_Positon + MRVBF + NDVI + TWI, data = DSM_data, method = "lm")
# or 2.
fit <- train(x = DSM_data[, c(6, 7, 8, 9, 11, 12, 13, 14)], y = DSM_data$pH60_100cm, 
              method = "lm")
```

Using the `summary(fit)` command brings up the model parameter estimates, while the object `fit` also contains a summary of some useful model goodness of fit diagnostics such as the RMSE and $R^2$ statistics. You can control how model validation is done where options include simple goodness of fit calibration, k-fold cross-validation, and leave-one-out cross-validation. This option is controlled using the parameter `trControl` in the `train` function.

The example below illustrates a 5-fold cross validation of a linear regression model with 10 repetitions.

```r
fit <- train(x = DSM_data[, c(6, 7, 8, 9, 11, 12, 13, 14)], y = DSM_data$pH60_100cm, 
              method = "lm", trControl = trainControl(method = "repeatedcv", number = 5, 
                                                        repeats = 10))
```

```r
fit
## Linear Regression
##
## 506 samples
## 8 predictor
##
## No pre-processing
## Resampling: Cross-Validated (5 fold, repeated 10 times)
## Summary of sample sizes: 404, 405, 405, 405, 405, 404, ...
## Resampling results:
##
##   RMSE   Rsquared
##  1.186   0.2312
##
## Tuning parameter 'intercept' was held constant at a value of TRUE
```

There are a lot of potential models that you could consider too for DSM. Check out [http://topepo.github.io/caret/modelList.html](http://topepo.github.io/caret/modelList.html) or print them.
as below:

```r
list_of_models <- modelLookup()
head(list_of_models)
```

```markdown
<table>
<thead>
<tr>
<th>model parameter</th>
<th>label</th>
<th>forReg</th>
<th>forClass</th>
<th>probModel</th>
</tr>
</thead>
<tbody>
<tr>
<td>ada</td>
<td>iter</td>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>ada</td>
<td>maxdepth</td>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>ada</td>
<td>nu</td>
<td>FALSE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>AdaBag</td>
<td>mfinal</td>
<td>FALSE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>AdaBag</td>
<td>maxdepth</td>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>9</td>
<td>adaboost</td>
<td>nIter</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

# The number of models caret interfaces with
def(list_of_models)
```

```r
nrow(list_of_models)
## [1] 452
```

You can choose which model to use in the `train` function with the `method` option. You will note that the fitting of the Cubist and Random Forest models below automatically attempt to optimise some of the fitting parameters, for example the `mtry` parameter for Random Forest. To look at what parameters can optimised for each model in caret we can use the `modelLookup` function.

```r
# Cubist model
modelLookup(model = "cubist")
```

```markdown
<table>
<thead>
<tr>
<th>model parameter</th>
<th>label</th>
<th>forReg</th>
<th>forClass</th>
<th>probModel</th>
</tr>
</thead>
<tbody>
<tr>
<td>cubist</td>
<td>committees</td>
<td>TRUE</td>
<td>FALSE</td>
<td>FALSE</td>
</tr>
<tr>
<td>cubist</td>
<td>neighbors</td>
<td>TRUE</td>
<td>FALSE</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

```r
fit_cubist <- train(x = DSM_data[, c(6, 7, 8, 9, 11, 12, 13, 14)],
                    y = DSM_data$pH60_100cm,
                    method = "cubist", trControl = trainControl(method = "cv", number = 5))
```

```r
# random forest model
modelLookup(model = "rf")
```

```markdown
<table>
<thead>
<tr>
<th>model parameter</th>
<th>label</th>
<th>forReg</th>
<th>forClass</th>
<th>probModel</th>
</tr>
</thead>
<tbody>
<tr>
<td>rf</td>
<td>mtry</td>
<td>TRUE</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

```r
fit_rf <- train(x = DSM_data[, c(6, 7, 8, 9, 11, 12, 13, 14)],
                 y = DSM_data$pH60_100cm,
                 method = "rf", trControl = trainControl(method = "cv", number = 5))
```

Using the fitted model, predictions can be achieved with the `predict` function:

```r
# Cubist model
pred_cubist <- predict(fit_cubist, DSM_data)
```

```r
# To raster data
pred_cubistMap <- predict(hunterCovariates_sub, fit_cubist)
```

There is plenty of other added functionality of the `caret` package. In addition to the detailed resources mentioned above, it always pays to look over
the help files that are associated with each function.
